NEXABI · ROLE GUIDE

# Three doors in

NexABI sells property in instalments and runs an intelligence layer over the business that results. Three kinds of people sign in and each one sees a different product built from the same rows — a buyer paying off a flat, a realtor bringing buyers in, and the operator approving, collecting and deciding. This is what each of them can do, and what each of them deliberately cannot.

Visitor · Buyer · Realtor · Operator · Who can see what · The rules underneath

## One journey, four hands on it

Every row in the system is created by somebody at one of these steps. The role guide below is really a guide to who holds the pen when.

1. 01
### Enquiry
An advert or a realtor's link brings someone to the questionnaire. It writes a lead — deliberately not an account.

VISITOR

2. 02
### Registration
State, LGA, income band, occupation and how they heard of us. A referral code attaches a realtor.

BUYER

3. 03
### Commitment
They pick a property and a term. The unit is **held**, not sold — nobody else can commit to it.

BUYER

4. 04
### Approval
An operator checks a realtor is attached, then approves. The plan opens

5. 05
### Instalments
The buyer transfers, an operator records each one, and the progress table fills.

6. 06
### Ownership
The last instalment settles the commitment on the

| | | |
|---|---|---|
| and the commission rate freezes.<br>OPERATOR | BUYER · OPERATOR | spot. Commission moves from owed to paid.<br>EVERYONE |

## 00 The visitor `no account`

Anyone who lands on the site

The catalogue is open. A property platform that demands registration before it will show a price is one people leave — the price is the reason they came, and withholding it buys an email address at the cost of the visit.

### Browse the whole book

All 700 units with the price *and* the monthly figure on every card. No sign-up wall, no "request price" form.

### Move the term picker

On any property, drag the term from 3 to 60 months and watch the monthly figure change. That number is the whole decision, so it is never behind a submit button.

### Send an enquiry

The questionnaire asks name, contact, budget and what they are looking for. It creates a *lead*, not an account — someone answering an advert is not ready to choose a password.

### Arrive through a realtor

A link carrying `?ref=CODE` attributes them to that realtor from the first click, rather than reconstructing it later.

## 01 The buyer `/portal`

357 on the platform

Someone paying off a property over a term they chose. One question brought them here — is anything owed, and when — and the overview answers it in a

sentence before anything else on the page loads.

### See where they stand, first

A banner that changes with the actual state of the account: settled, on schedule, due soon, or behind — and if behind, what it costs and how to fix it.

### Browse and commit without leaving

The same stock as the public catalogue, inside the portal. Committing holds the unit and opens a request; it does not buy anything until an operator approves it.

### Watch every payment land

The progress table shows each instalment, its due date and its live status. Paid, due, overdue and scheduled are worked out from today's date every time the page is read.

### Reach their realtor from anywhere

A bar pinned under the navigation on *every* portal page carries their realtor's name, phone and email.

A buyer looking at a ₦90m flat has questions the software cannot answer — is the road tarred, what is the service charge, can I view it Saturday. Putting the person who can answer behind a Support tab means the question gets asked to nobody.

AI · ASK NEXABI

### Work out what they can actually afford

Buyers know what they can pay *each month*, not what they can pay in total. A price filter asks them to do the division themselves and get it wrong.

So affordability is computed, not narrated — it finds the real units that fit the figure, at the longest term each one offers, and lists them with a link straight to commit.

> What can I afford at 3 million a month?

**120 properties fit ₦3,000,000 a month** — across Ajah, Yaba, Chevron

### Documents and support

Their file, and a ticket form that emails their own realtor with reply-to set to the buyer — plus a receipt to the buyer so they know it went somewhere.

and Gbagada. Figures are at the longest term each property offers; a shorter term costs more monthly and hands over sooner.

› Will Lekki go up in value?

**I don't have the data for that.** Nothing in this platform knows whether an area is a good investment, and a confident answer would be a financial opinion dressed up as a calculation. Your realtor can talk about the area.

## 02 The realtor /realtor

118 approved · 2 awaiting approval

A realtor runs a small business inside a bigger one. They bring buyers in with their own link and earn a commission that is frozen onto each sale the moment it is approved — so nothing that happens to a listing afterwards can change what they are owed.

BEFORE APPROVAL

### One screen, and only one

Signing up creates the account; an admin approving it creates a realtor who can do anything. Until then there is no code, no leads, no catalogue — every other realtor URL redirects back to a holding screen that says what happens next.

The gate lives in middleware rather than in each page, so there is no route where somebody could forget it.

### A code and a link

Issued at approval, not at signup — an unapproved realtor handing out links would be collecting registrations nobody has vetted. The code avoids characters that get misheard down a phone line: no 0/O, 1/I/L, 5/S or 8/B.

### Their own leads

Everyone who arrived through their link, plus anyone they recorded by hand. Never another realtor's book.

### Commission shown per unit

The full catalogue with what each sale would actually pay them, so choosing what to push is an informed decision rather than a guess.

### Materials, already personalised

Flyers, social images, brochures and message templates written once by the operator and downloaded by each realtor with their own name, number, code and link already in them. A corrected price is fixed in one place instead of a hundred.

AI · ASK NEXABI

### Where to point the effort

Two rules shape every answer. **Demand is market-wide**, because that is the signal a realtor is paying attention for. **Performance is theirs alone** — no route returns a colleague's numbers and the facts sheet carries no other names.

› `Which location should I focus my marketing on?`

**Lekki is where the pressure is.** 191 buyers asked for Lekki in the last four months against 34 units on the shelf — roughly 5.6 buyers per unit. Average stated budget ₦139.1M, and stock there starts at ₦50,000,000.

› `Which areas are buyers becoming interested in?`

**Interest is moving towards Lekki** — 191 buyers in the last four months against 164 in the four before, a swing of +27. Most-requested type overall is Apartment, average budget ₦168.5M.

› `Who is the best realtor in the company?`

**I don't have the data for that.** Refused by design — and there is a

test that fails if any colleague's name appears in an answer.

### A statement they can check

Commission earned, paid and owed, line by line against the sales that produced it — with the rate that was frozen at approval shown on each one.

## 03 The operator `/app`

Six seats across four role lenses

The agency side. Two queues are most of the day, and an intelligence layer surfaces the rest without waiting to be asked. The role lens re-ranks what an operator sees; it never filters it, so a finance risk does not stop existing when a sales manager signs in.

QUEUE ONE

### Commitments awaiting approval

A table with a side canvas. Approving generates the instalment plan and freezes the commission rate — so it refuses while the buyer has no realtor attached, and offers a searchable picker to fix that in the same panel.

QUEUE TWO

### Realtors awaiting approval

Approve and the code is minted and emailed. A realtor sitting unapproved for three days is three days of leads nobody captured, so pending always floats to the top of the table whatever the sort.

### Finance and collections

Receivables aged into buckets, instalments recorded with a reference and a recorder, reversals for mis-keys, and commission owed against paid.

### Properties and marketing

Add stock with photographs uploaded or linked, set commission and term bounds. Record offline marketing — a billboard, a radio read, a church announcement —

with what it cost and what it was promised to deliver.

AI · THE INTELLIGENCE LAYER

### Findings that arrive on their own

Fourteen detectors sweep nine metric groups every fifteen minutes. Each finding says what is happening, what it means and what to do — and the one screen built for deciding carries a button that does it.

Applying it moves real rows, logs a before-and-after diff, and the finding retires itself because the condition stopped holding. If nothing actually changed, it stays.

› Finding · critical

**171 of your highest-scoring leads haven't been contacted in a week** → Contact all 171 today

› Finding · critical

**3-bed Apartment in Lekki is drawing 12.2× normal demand on 4 units of stock** → Raise asking price 6% on the 4 remaining units

› How much is overdue?

**₦5.3B** across 41 instalments and 41 accounts. ₦3.2B has aged beyond 90 days. Total outstanding including not-yet-late is ₦5.6B.

### Everything is auditable

Every applied action is logged with who did it, what changed, and the measured difference. The action log is opened from a finding rather than browsed.

## 04 Who can see what

Enforced in middleware, not in pages

Signing in as one kind of account and typing another area's URL walks you back to your own front door rather than showing an error — a realtor who bookmarks /app has made a navigation mistake, not an attack. Every rule below has a test that fails if it stops holding.

| CAN THEY… | VISITOR | BUYER | REALTOR | OPERATOR |
|---|---|---|---|---|
| **Browse the catalogue and see prices** | Yes | Yes | Yes | Yes |
| **Commit to a property** | No | Yes | No | No |
| **See their own payment schedule** | n/a | Yes | n/a | All of them |
| **See another buyer's schedule** | No | No | No | Yes |
| **See their own leads and commission** | n/a | n/a | Yes | All of them |
| **See another realtor's book** | No | No | No | Yes |
| **Ask the AI about market demand** | No | Prices & areas | Yes | Yes |
| **Approve a commitment or a realtor** | No | No | No | Yes |
| **Record an instalment as received** | No | No | No | Yes |
| **Apply a recommendation that changes data** | No | No | No | Yes |

> **A buyer cannot buy without a realtor attached — but is never turned away for arriving without one**

> Registration accepts anyone. Someone who found the platform on the radio and has no referral code becomes a real buyer with no realtor yet, and lands in the unassigned queue an operator works through. The guarantee is not "you cannot register without a realtor" — it is that **no instalment plan ever opens without one**, enforced at approval, because commission has to have an owner and nothing downstream could work out who it belonged to later.

## 05 The rules underneath

The same for every role

Three decisions that shape everything above. Each is a thing most software gets wrong by default, and each has a test that fails if it stops being true.

RULE 01

### A payment's status is always live

Worked out from the due date against the clock, every single time it is read. Store it instead and an instalment three weeks past due keeps reporting itself as on schedule — the kind of quiet wrongness that permanently costs a buyer's trust in a payments screen.

RULE 02

### A commission rate is always frozen

Copied onto the sale the moment it is approved, and read from there for ever after. Editing a listing next year must never rewrite money a realtor has already earned. A test changes a rate after approval and fails if the earned figure moves.

RULE 03

### The AI never sees a raw row

Every model call receives figures the metrics layer has already computed — never records. It phrases; it cannot invent. And when the figures do not cover the question it returns a sentinel, so "I don't know" is a real answer rather than a fluent guess.

Figures read from the live database
